

Data Structures and State Management

Documentation Write-up

To manage the player's state, I created a dedicated C++ class to store stats like Health, Rage, and Eloquence, which kept the data protected so it could only be updated through specific functions like taking damage or healing.

For the inventory, I used a `std::map` dictionary structure that links an item's name directly to how many the player currently owns. This setup was really efficient for my turn-based Western game because I didn't want to loop through a basic array every time a move was made. Instead, the map allows the game to instantly check if the player actually has game items such as the 'Cortisol Pills' or a 'Megaphone' right in the middle of combat, keeping the underlying code fast and organized.
